

Fauna, Distribution, Habitat Preference and Abundance of Woodlice (Oniscidea) in Latvia

VOLDEMĀRS SPUNGIS

Department of Zoology and Animal Ecology, Faculty of Biology, University of Latvia, 4 Kronvalda Blvd., LV-1586, Rīga, Latvia, e-mail: adalia@lanet.lv

SPUŅĢIS V. 2008. FAUNA, DISTRIBUTION, HABITAT PREFERENCE AND ABUNDANCE OF THE WOODLICE (ONISCIDEA) IN LATVIA. – *Latvijas entomologs*, 45: 25-37.

Abstract: In total, 20 woodlice species are known in the territory of Latvia. *Haplophthalmus danicus* is recorded for the first time. Distribution, habitat preference and abundance data of species are presented.

Keywords: Isopoda, Oniscidea, fauna, distribution, abundance, Latvia.

Introduction

Woodlice (Isopoda, Oniscidea) are common invertebrates in Latvia. The population density of woodlice can be high in favourable conditions, and thus they could play an important role in the decomposition of detritus.

These terrestrial crustaceans were investigated in Latvia for long time. W.Herold (1927) studied Latvian and Estonian fauna in 1924-1928. He recorded 14 species. The data from Latvia were fragmentary. Later G.Glikmanis (1935) investigated the fauna and habitat preference of woodlice in Latvia in 1927-1933. He added 5 new species to the fauna of Latvia. G.Glikmanis developed graduate theses in Latvian. The results of the research were not published. Thus the information was not available for the wider scientific public. No specimens mentioned in the theses are deposited in the museums of Latvia. Most obvious the collection was lost and there is no possibility to prove the correctness of identification in line with modern taxonomy on Oniscidea. All later publications (Tauriņš, Ozols 1957, Spuris 1974) were based on these theses.

Up to now 19 species of woodlice are known in Latvia. The fauna and population density of woodlice need to be thorough investigated because of their significant role in decomposition of plant litter.

Methods

The main faunistic investigations of woodlice have been performed in 2003-2007 by the author. Different methods were used: pitfall trapping (diameter of the opening 7.5 cm, 10, 15 or 30 traps were arranged on transect in the investigated habitats, exposition period lasted 7, 14 or 28 days); sampling and sieving of litter in different forests; direct searching of woodlice in the dead wood; accidental sampling in various habitats. The abundance of woodlice (ind./trapweek) was calculated for data obtained by use of pitfall traps. The material collected by other methods could not be used to characterise abundance, because number of recorded individuals depended on sample size, collection season and experience of researcher. The materials collected by numerous other researchers were also investigated.

To estimate habitat preference and relative abundance, the faunal data were analysed taking into consideration presence of species in particular habitats and number of collected individuals. In all cases the number of collected specimens depended on sampling effort and obtained data cannot be used for deeper ecological analysis. The relative occurrence of woodlice in the particular habitat type was expressed in three classes: 1 – rare (single individuals in one or few localities); 2 – common (several individuals in few to many localities); 3 – very common (numerous individuals in numerous localities).

The woodlice were preserved in 80% ethyl alcohol and stored in Eppendorf vials or larger plastic vials depending of sample size. The species were identified by use of keys (Gruner 1966, Hopkin 1991). A collection of investigated woodlice is deposited in the Department of Zoology and Animal Ecology, Faculty of Biology, University of Latvia.

Abbreviations used in the text: R. – references; M. – collected material; distr. – district (underlined); ind. – individual(s); n. – numerous individuals. The species were listed by their taxonomy (Gruner 1966), the localities – alphabetically by districts (underlined) and toponyms, the recording dates – chronologically. Data about habitats and number of collected individuals were added. The author collected the majority of the material, except if mentioned otherwise in the text.

Remarks. The species is very common in the

moist to wet deciduous, mixed and spruce forests, floodplain forests, and wet calcareous meadows and fens as well. Litter dwelling. W.Herold (1927) and G.Glikmanis (1935) recorded the species in numerous localities all around Latvia in the appropriate habitats.

Trichoniscidae

***Haplophthalmus mengei* (ZADDACH, 1844)**

R. Glikmanis 1935 (*H. mengii*), Tauriņš, Ozols 1957.

M. Aizkraukle distr.: Pērse river valley, 08.10.2005, calcareous deciduous forest, 1 ind. Alūksne distr.: Vireši, Randatu cliffs, 17.08.2006, calcareous deciduous forest, 3 ind. Riga distr.: Doles sala, 20.08.2007, calcareous deciduous forest, 2 ind.

Remarks. The species is rare. Woodlice definitely prefer calcareous deciduous forests in the river valleys with dolomite outcrops. W.Herold (1927) reported species from Koknese (Daugava river valley), G.Glikmanis (1935) – from Pērse river valley at Koknese, (Daugava river valley) and from Abava river valley at Kandava and Kalnamuiža (Venta river valley).

***Haplophthalmus danicus* BUDDE-LUND, 1879**

M. Kuldīga distr.: Alsunga, 22.10.2006, oak-pine forest, 7 ind. Riga city: Botanical garden of University of Latvia, 04.05.2003, in greenhouses, 1 ind., Kronvalda park, 27.10.2004, deciduous park, 6 ind. Tukums distr.: Pliņciems dune, 10.07.2005, rotten birch wood, 1 ind.

Remarks. The species is new to the fauna of Latvia and is very rare, probably synanthropic. The species was found in the botanical garden, near the settlement and near the graveyard.

***Hyloniscus riparius* (C.L.KOCH, 1838)**

R. Glikmanis 1935 (*H. vividus* Verh.), Tauriņš, Ozols 1957 (= *H. vividus* Verh.).

M. Liepāja distr.: Grobiņa, 18.10.2003, deciduous park, 10 ind., Pērkone, 21.09.2003, deciduous forest in the dune slack, 1 ind.

Remarks. The species is rare in Latvia. G.Glikmanis (1935) has found species in Paurupe and Bārta river valleys, Rucava and Pape (all in Liepāja district), but always in wet habitats. In accordance with historical and

recent data the species is restricted to utmost South-West of Latvia.

***Trichoniscus pusillus* BRANDT, 1833**

R. Herold 1927 (*T. elisabethae* var. *estoniensis* HEROLD, 1926 nov. var.), (*T. (Spiloniscus) pusillus coelebs* (VERHOEFF), Glikmanis 1935 (*T. elisabethae*, *T. pusillus coelebs* VERHOEFF, 1917), Tauriņš, Ozols 1957 (= *T. pusillus coelebs* VERH.).

Riga distr.: Doles sala, 20.08.2007, calcareous deciduous forest, 6 ind.; Ķekava, 26.05.2005, white alder forest, 4 ind.; Ķemeri, 12.10.2005, black alder floodplain forest, n (10) ind.; Lielie Kangari, 30.04-27.05.2006, pitfalls, mixed wet calcareous forest, 5 ind., 27.05.2006, rotten deciduous wood, 5 ind.; Salaspils, 07.10.2004, deciduous forest, n (10) ind., 22.09.2005, wet calcareous pine forest, n (13) ind., 10.10.2005, deciduous forest, n (15) ind., 27.09.2006, wet calcareous pine forest, 3 ind.; Tumšupe river valley, 27.05.2005, white alder floodplain forest, 8 ind. Saldus city: Ciecere river valley, 22.10.2005, deciduous forest, n (20) ind. Saldus distr.: Zvārde, Īves, 11.06.2006, calcareous meadow, 3 ind.; Zvārde, Zvārde church, 13.05.2006, black alder forest, 4 ind. Talsi distr.: Dundaga, 28.10.2006, deciduous park, 6 ind.; Slītere, 11-18.07.2004, pitfalls, broadleaved forest, 7 ind., wet spruce forest, 3 ind. Tukums distr.: Čužu bog, 21.05-18.06.2005, pitfalls, calcareous fen overgrown with *Potentillafruticosa*, 32 ind.; Kandava, 16.10.2005, calcareous deciduous forest, 4 ind.; Kanieris lake coast, 12.06.2005, deciduous forest, 1 ind., mixed forest, 1 ind.; Pliņciems dune, 10.07.2005, rotten birch wood, 2 ind.; Slampe, 20.10.2006, deciduous forest, 6 ind. Valmiera distr.: Mellupīte river mouth, 29.10.2005, broadleaved forest, 7 ind. Ventspils distr.: Rīva river mouth, 28.10.2006, deciduous forest, 2 ind.

Remarks. The species is very common, prefers different deciduous forests, particularly wet and calcareous ones, can be found also in wet calcareous meadows and rotten wood, rarely – in coniferous forests, but absents in dry habitats and bogs. Usually it is abundant. W.Herold

(1927) and G.Glikmanis (1935) stated that species is widely distributed and mentioned numerous localities. The species is parthenogenetic, because there are only 1-2 males per 1000 females. G.Glikmanis discovered males attributed to the species *T. elisabethae* Herold, 1923. At the same time he stated that *T. elisabethae* had the same habitat requirements as *T. caelebs* and can be found in the same locality. All recently recorded individuals belonged to *T. elisabethae*.

Ventspils distr.: Irbe river valley, 14.05.2003, rotten pine wood, 1 ind.; Pope, 31.07.2003, *Molinia caerulea* meadows, 2 ind.; Rīva river mouth, 28.10.2006, deciduous forest, 5 ind.; Usma, 13.08.2006, rotten deciduous wood, 2 ind.

Remarks. The species is numerous in the rotting deciduous wood, in the soil of deciduous forests, deciduous floodplain forests, calcareous fens and along water bodies. Less numerous species is in the cultivated meadows, coniferous forests, very dry and very wet habitats. Fewer individuals were collected in the Eastern and Northern parts of Latvia. W.Herold (1927) and G.Glikmanis (1935) reported species as common and widely distributed, particularly in wet habitats connected with water bodies.

***Porcellium conspersum* KOCH, 1841**

R. Herold 1927, Glikmanis 1935, Tauriņš, Ozols 1957.

M. Jelgava distr.: Vilce, 01-28.05.2006, pitfalls, broadleaved floodplain forest, 20 ind.

Remarks. The species is rare and connected mostly with calcareous deciduous forests. Previously species was found in the western and central part of Latvia and along Daugava River. W.Herold (1927) and G.Glikmanis (1935) reported species from numerous localities in Western Latvia and along Daugava river valley.

Tukums distr.: Pliņciems dune, 11.06.2005, rotten pine wood, 14 ind., 10.07.2005, pine forest, 9 ind., rotten pine wood, n (30) ind., 12.10.2005, calcareous pine forest, n (7) ind.; Sēme, 12.06.2005, deciduous park, 4 ind.

Remarks. The species is rather common and distributed in the whole Latvia, but is most common in the Central and Western districts and along the Daugava and Lielupe rivers. Prefers calcareous meadows and deciduous forests. Individuals can be found both in rotten wood and litter. Locally could form abundant populations. W.Herold (1927) and G.Glikmanis (1935) reported species from numerous localities.

***Armadillidium zenckeri* BRANDT, 1833**

R. Herold 1927, Glikmanis 1935.

M. Talsi distr.: Dundaga, 28.10.2006, deciduous park, 1 ind. Tukums distr.: Antiņciems, 19.09.2003, calcareous fen, 5 ind.; Kanieris lake coast, 16.04.2005, calcareous deciduous forest, 2 ind., 12.10.2005, calcareous fen, 10 ind.

Remarks. The species is rather rare in Latvia and definitely prefers calcareous deciduous

forests. W.Herold (1927) and G.Glikmanis (1935) reported species from numerous localities.

***Armadillidium opacum* (KOCH, 1841)**

R. Herold 1927, Glikmanis 1935.

M. Liepāja distr.: Rucava, Līgupīte river coast, 16.10.2005, deciduous floodplain forest, 4 ind. Riga city: Botanical garden of University of Latvia, 15-29.11.2004, pitfalls, greenhouses, 1 ind. Remarks. The species is rather rare, prefers deciduous forests and tent to be synanthropic. Individuals were not found in natural forests outside settlements. W.Herold (1927) and G.Glikmanis (1935) reported species from numerous localities in the Daugava river valley.

***Porcellio dilatatus* BRANDT, 1833**

R. Glikmanis 1935.

M. Tukums distr.: Pļieņciems dune, 10.07.2005, rotten pine wood, 1 ind.

Remarks. The species is rare in Latvia. The ecological data are insufficient. G.Glikmanis (1935) recorded species in Rīga and Jaunjelgava.

***Porcellio laevis* LATREILLE, 1804**

R. Glikmanis 1935 (*Porcellio*).

Remarks. No recent records. The species is rare in Latvia. The ecological data are insufficient. G.Glikmanis (1935) recorded species in Rīga and Aizpute.

***Porcellionides pruinosus* (BRANDT, 1833)**

R. Herold 1927 (*Porcellio (Metoponorthus)*), Glikmanis 1935 (*Porcellio (Metoponorthus)*), Tauriņš, Ozols 1957 (*Metoponorthus*).

Remarks. No recent records. The species is rare and distributed sporadically in the whole Latvia. W.Herold (1927) and G.Glikmanis (1935) reported species from numerous localities.

Habitat preference, occurrence and relative density of woodlice in the habitats

Woodlice selected habitats specific for particular species and every species occurred more frequently in the definite habitats (Table 1).

Table 1. Occurrence of the woodlice species in various habitats.
Explanations: 1 – rare; 2 – common; 3 – very common; ? – data deficient.

Discussion

Fauna and distribution

In total, 20 species of woodlice are known in Latvia. *Haplophthalmus danicus* is recorded for the first time. The number of recorded species decreases from the Western part of Latvia to the Eastern part. Western part of Latvia is rich with calcareous forests, meadows and fens, and climate is rather mild in comparison with the Eastern part. That explains higher species diversity in the Western Latvia. Two species – *Hyloniscus riparius* and

Philoscia muscorum – are restricted to the South-West of Latvia. Daugava river valley rich with calcareous habitats is another important boarder of distribution of woodlice. For example, species of the genus *Armadillidium* mostly are distributed in the valley of this river and southwards. In the North of Latvia only widely distributed and ecologically plastic species were recorded, for example, *Trachelipus rathkii*. Negative results of the searching of woodlice could give good proof for this statement, but unfortunately they were not documented. *Porcellio scaber* has specific

distribution: these woodlice are common and numerous in the Maritime Lowland along the Baltic Sea coast, but become rare in inlands.

In comparison with the other Northern European countries (Silfverberg 1999) the species diversity in natural habitats of Latvia is known completely. Some more species could be found in the greenhouses and hatcheries.

The woodlice fauna in Latvia are mostly represented by typical West and Middle European species (Gruner 1966) with some exceptions. *Haplophthalmus danicus* is Holarctic species, *Porcellionides pruinosus* Palaearctic – species. *Philoscia muscorum* and *Hyloniscus riparius* are the South to Central European species and thus restricted to the South-West of Latvia. *Cylisticus convexus* is originally Pontic species and is distributing rapidly. The southern and Atlantic species have tendency to live in the synanthropic habitats as graveyards and parks, for example, *Porcellio dilatatus*, *Cylisticus convexus* and *Haplophthalmus danicus*.

Habitat preference and abundance of woodlice in the habitats

The woodlice prefer mostly different deciduous forests where the highest species diversity was stated. Calcareous moderately wet deciduous forests have the highest diversity of woodlice. Daugava and Venta river valleys were most important in maintaining high species diversity, while Lielupe and Gauja river valleys was less important. The microhabitats of the species were mostly dead wood. That explains the occurrence of species sometimes in the inappropriate habitats, e.g., pine forests. Deciduous parks in the settlements in some respect imitate deciduous forests, thus explains high species diversity in the parks. Open habitats like meadows and fens with no trees usually have less number of species and possessed mostly ubiquitous species, like *Trachelipus rathkii*. Raised bogs are the single habitat where woodlice were not found.

The abundance can be estimated for larger in size woodlice, like *Porcellio* species or *Trachelipus rathkii* and some other soil dwelling species. *Trachelipus rathkii* is the most common epigeic woodlice and is distributed commonly in a wide variety of habitats.

Ligidium hypnorum has rather high abundance in different forest habitats, particularly in the moderately wet or wet forests. This species is absent in pine forests, most probably because of acid soil conditions. Small in size woodlice *Trichoniscus pusillus* cannot be trapped efficiently by use of pitfall traps. Direct observations indicated that these woodlice are common, but are not true epigeic species. They usually try to shelter in the detritus. The species connected with decaying wood like *Oniscus asellus* or *Armadillidium* species usually present in the pitfall traps in an insignificant numbers. These records do not reveal the actual abundance of saproxylic woodlice. Really, the pitfall trapping can be used only for monitoring of two species, *Trachelipus rathkii* in different habitats and *Ligidium hypnorum* in different deciduous forests.

Acknowledgements

I thank G.Akmentiņš, I.Cera, L.Irša, M.Kalniņš, E.Parele, K.Vilks, E.Vimba and D.Trušelis for collecting of woodlice and providing them for identification.
